The measurements of the two species appear to vary but little, the four examples of $A$. cerviniventris now before me ranging in length of wing from 2.15 to 2.30 inches, while the type of $A$.yucatanensis measures 2.20 ; the length of tail in the latter is 1.60 , and in the former series varies from 1.50 to 1.70 . The culmen ranges from .70 to .80 in cerviniventris, but the bill of the type of yucatanensis is unfortunately broken, so that its length cannot be ascertained.
A. cerviniventris appears to be exclusively an eastern species (as are also A. yucatanensis and A. fuscicuuduta), its habitat extending from southeastern Texas to Vera Cruz, and perhaps also to Yucatan, since Mr. Elliot (Synopsis, 1. 219) states that he "can perceive no difference between Mexican and Yucatan specimens". The $A$. cinnamomea appears to be wanting from eastern Mexico, but in the collection of the National Museum are specimens from Mazatlan, Tehuantepec, and Yucatan, besides San Salvador and Nicaragna, thongh Mr. Elliot gives only "Guatemala and Costa Rica" as its habitat.

##   CEENUTASHE J.ANEG.

## By TARELETON H. BEAN.

The first two species here mentioned as undescribed formed part of a collection received from Capt. Charles Bendire, U. S. A. Several other species received at the same time are retained for study and comparison with fuller material promised from the same source.
The Myetophum was obtained by Mr. W. H. Dall, in the Pacific, off Puget Sound.
Uranidea marginata, n. s.
24197; 9 specimens; tributaries of Walla Walla River; Capt. Charles Bendire, U. S. A.
B. VI; D. VII-VIII, 18-19; A. 15-14 $\frac{1}{1}$; V.I, 3; P. 13-14; C. 14-15.

This species is allied to Cottus cognatus Rich., but differs from that species in having the vent nearer to the insertion of the candal than to the snont, while the origin of the anal falls in the vertical from the third dorsal ray instead of the sixth, as in Richardson's species. The rentral has 1 spine and 3 rays ( $O$. cognatus has 1 spine and 4 rays). The longest pectoral rays are shorter than the head (equal to the head in cognatus).

Head broad, slightly depressed, its greatest length contained a little more than 3 times in length of body without caudal ( 4 times in total length); distance from tip of snont to eye equals length of eye, which is $\frac{1}{4}$ of length of head. Vomerine teeth; none on the palatines. Body stout anteriorly, moderately compressed posteriorly, its height at origin of first dorsal equal to its width at the same place, and contained $4 \frac{1}{2}$ times in length of body without candal; the least width of the candal peduncle
less than $\frac{1}{2}$ its height. The distance between the eres equals $\frac{1}{2}$ of their long diameter. The maxilla extends to the vertical throngh the end of the anterior third of the orbit. The preoperculum has a short, broad, rather blunt spine at its angle and a much smaller one on its lower limb; between these two the margin in some specimens is crenulated, sometimes forming an additional blunt spine. The preopercular spines are all hidden under the skin.
The distance of the first dorsal from the snout is contained $2 \frac{2}{3}$ times in length of body without caudal; its longest spine is $\frac{1}{3}$ as long as the head; the length of its base is contained 5 times in length of body without candal, 6 times in total length; the length of the second dorsal base is $\frac{1}{3}$ of total length. The length of the anal base is $\frac{1}{3}$ of length without caudal. The length of the ventral is contained from 6 to $6 \frac{1}{2}$ times in the total length. The length of the pectoral is $\frac{1}{4}$ of length of body without caudal.
The colors have faded, but the ground color seems to be plumbeous, with occasional blotehes of darker. The fins are more or less distinetly punctulated. The first dorsal is darker than the body aud has a distinet white margiu.

Potamocottus Bendirei, 11. s.
The type of this species, catalogue No. 24196, was collected by Capt. Charles Bendire, U. S. A., in Rattlesnake Creek, near Camp Harney, Oregon, May 2, 1878. I take pleasure in dedicating the species to this excellent collector and observer, who has contributed so much to the Musenm.

Description.-The length of the type is 2.7 inches ( $\left.69^{\mathrm{mmu}}\right)$ to base of caudal. The greatest height of the body at the origin of the dorsal equals its greatest width over the base of the pectorals, and is contained nearly 4 times in its length withont candal. The least height of the tail is $\frac{1}{12}$ of the length without caudal. The length of the middle caudal rays is contaned $\frac{1}{2}$ times in length of body.* Width of the mouth equals $\frac{1}{2}$ the length of the head.
The maxillary extends a little behind the front margin of the ere. The snout is as long as the eye. The distance between the eyes is less than their diameter, and is contained 5 times in the length of the head; the diameter of the eye 4 times. The length of the lower jaw equals $\frac{1}{2}$ the length of the head. Preoperculum armed with 4 spines; the largest is at the angle, and is about $\frac{1}{2}$ as long as the eye; the 3 anterior ones are very small and hidden by the skin. The distance of the spinous dorsal from the snont is $\frac{1}{3}$ of the length of the body; the length of the longest spine of the first dorsal is about $\frac{1}{3}$ of that of the head and about $\frac{2}{3}$ of the longest dorsal ray. The lougest dorsal and anal rays are equal. The length of the anal base almost equals the length of the head. The length of the second dorsal base is a little greater than the length of the head.

[^0]The pectorals reach to the origin of the anal; ventrals do not reach to the vent.

Vomerine and palatine teeth present. Skin smooth.
Radial formula: B. VI; D. VIII, 16; A. 12; V. I, 3; P. 15; C. $1 \overline{5}$.
Color: Uniform dark brown above, lighter on the throat and belly.
Myctophum crenulare, J. \& G.
The musem has an additional specimen of this species, which was washed aboard a United States Coast Survey vessel commanded by Mr. William H. Dall, in N. lat. $49^{\circ}$, W. long. 1510. It was collected by Mr. W. G. Hall. The specimen is numbered 23945 in the National Museum Fish Catalogne.
Descripition.-D. I, 11; A. I, 16; P. 13; V. 7; seales 21-45-6 ${ }_{2}^{2}$.
The basis of comparison for the measurements of different parts of the body is the total length without caudal. The greatest height of the body is contained 4 times in this length, the length of the head $3 \frac{2}{3}$ times; the least depth of the tail equals $\frac{1}{4}$ of the height of the body at the ventrals, height of the head nearly equal to its length without suout. Eye large, its diameter being more than the interorbital distance, and contained 3 times in the length of the head. Posterior margin of the preopereulum oblique. Snout very short and obtuse, about $\frac{1}{3}$ as long as the eye. The maxillary is $\frac{2}{3}$ as long as the head, scarcely dilated posteriorly; it reaches almost to the posterior margin of the preoperculum. The origin of the dorsal fin is equally distant from the tip of the snont and the root of the candal, and is about over the tips of the extended ventrals; it is about in the vertical through the sixteenth scale of the lateral line; its last ray is over the twenty-fifth scale of the lateral line and the eighth anal ray. The pectorals are imperfect, but they apparently do not extend much beyoud the origin of the ventrals. Seales coarsely denticulated, some of them showing about 6 teeth on their free margin; those on the lateral line are conspicuously the largest. Lower parts with a double series of pearl-colored spots, besides a ferw isolated ones.

Measurements.

| Current number of specimen <br> Locality |  |  |
| :---: | :---: | :---: |

 STATES.

Hy DAVID S. JORDAN aUM CHARLES M. GHEBERE'.
It is the purpose of this paper to present a list of the species of fishes known to oceur along our Pacific coast, between the Mexican boundary and the boundary of British Columbia, together with notes on the distribution, habits, size, value, etc., of each species, in advance of the publication of a general descriptive work. The paper is to be considered mainly in the light of a contribution to our knowledge of the geographical distribution of fishes. The "common names" here given are, in all cases, those heard by the writers among the fishermen on different parts of the coast.

## Family BRANCHIOSTOMATIDA.

1. Branchiostoma lanceolatum (Pallas) Gray.

Obtained by Dr. J. G. Cooper in San Diego Bay. Not seen by us.

> Family MYXINIDAE.
2. Polistotrema dombeyi (Müller) Gill.-Lamperina; Hag; Eel.

Santa Barbara (fide J. Weinmiller) to Eel River (Lockington). Very abundant in the Bay of Monterey, but not taken elsewhere by us. It

[^0]:    * Length of body here means length without caudal.
